Text: Chapter 3, Sect 2-3 directly relates to this lecture, added material needed

III. C. Special Topics in optics

1. Linear Polarizers -- random polarization in - linear out (i.e. **E** field with specific orientation)

   a. Absorptive (or reflective -- for metal): Aligned dipole transitions select polarization

   -- vis & uv, *absorbing* (Polaroid, stretched film impregnated with dye, can be big, orient by

   binding to oriented polymer)—"glare" is polarized, sheets of Polaroid make sunglasses

-- IR: *reflection*: wire (grid) --made like a grating (narrow spacing $\lambda > 2d$),

   hologram expose photo resist, evaporate metal (Al or Au) across ridges,

   high groove density *minimize d for near IR*
*Wide acceptance angle, large aperture possible, low to moderate power*

Cambridge Physical Science (sold under various names) – Now Thorlabs.com lists them

http://www.thorlabs.com/NewGroupPage9.cfm?ObjectGroup_ID=1118

Wire Grid Polarizer Specifications

| Material	CaF_2		BaF_2		ZnSe		KRS-5	
Wavelength	3 μm	8 μm	3 μm	10 μm	3 μm	10 μm	3 μm	15 μm
Typical Extinction Ratio	150:1	300:1	150:1	300:1	150:1	300:1	150:1	300:1
Wire Grid Spacing (Nominal)	2700 Grooves/mm							
Parallelism	≤ 3 arcmin							
Surface Flatness	$\lambda/20$ @ 10.6 μm for Ø25 mm Polarizers $\lambda/10$ @ 10.6 μm for Ø50 mm Polarizers							
Substrate Thickness	2 ± 0.5 mm for Ø25 mm Polarizers 5 ± 0.5 mm for Ø50 mm Polarizers							
Ring Thickness	5.0 mm ± 0.2 mm							
Ring Diameter Tolerance	+0.0/-0.2 mm							
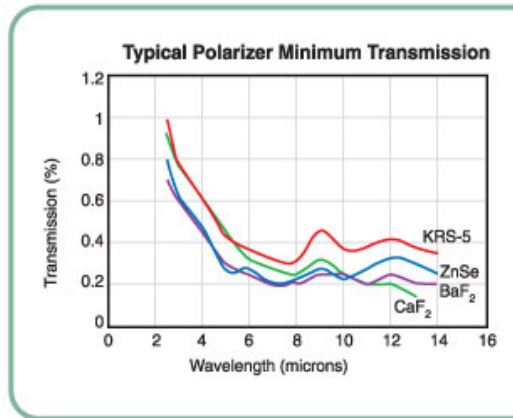

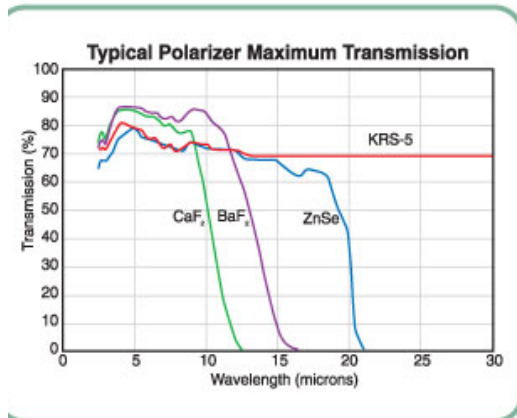

Substrates affect transmission, CaF_2 or BaF_2 for near IR, Ge mid IR,

   wire density controls polarization ratio (see below Cambridge Physical Science data)

Performance Specifications

MODEL NUMBER	IGP228 (BaF₂)	IGP227 (CaF₂)	IGP226 (Ge)	IGP225 (Krs 5)	IGP224	IGP223
Spectral Range	1-12 μm	1-9 μm	8-14 μm	2-35 μm	50-1000 μm	20-1000 μm
Substrate Material	Barium Fluoride	Calcium Fluoride	AR coated Ge	KRS-5	Polyester	Polyethylene
Substrate Thickness	2 mm	2 mm	2 mm	2 mm	2.5 μm	0.5 mm
Aperture	25 mm dia.	25 mm dia.	25 mm dia.	25 mm dia.	37 mm dia.	25 mm dia.
Transmission (k_i) Efficiency	85%	85%	90% (10 μm)	70% (10 μm) 50% (3 μm)	90%	80%
Grid Spacings (period)	0.25 μm	0.25 μm (approx)	0.4 μm (approx)	0.4 μm (approx)	10 μm	4 μm
Extinction Ratio	42 (3.9 μm) 14 (1.5 μm)	42 (3-9 μm) 14 (1.5 μm)	> 190 (10 μm)	>9 (3 μm) >140 (10 μm)	>15	>12 (20 μm) >20 (30 μm)
Degree of Polarization	98% (3.9 μm) 93% (1.5 μm)	93% (1.5 μm) 98% (3-9 μm)	>99% (10 μm)	>99% (10 μm) >88% (3 μm)	>93%	>92% (20 μm) >95% (30 μm)
Holder Diameter	1.625in(4.13cm)	1.625in(4.13cm)	1.625in(4.13cm)	1.625in(4.13cm)	2.125in(54cm)	1.625in(4.13cm)
Holder Thickness	0.25in(0.635cm)	25in(0.635cm)	25in(0.635cm)	25in(0.635cm)	25in0.635cm]	25in(0.635cm)
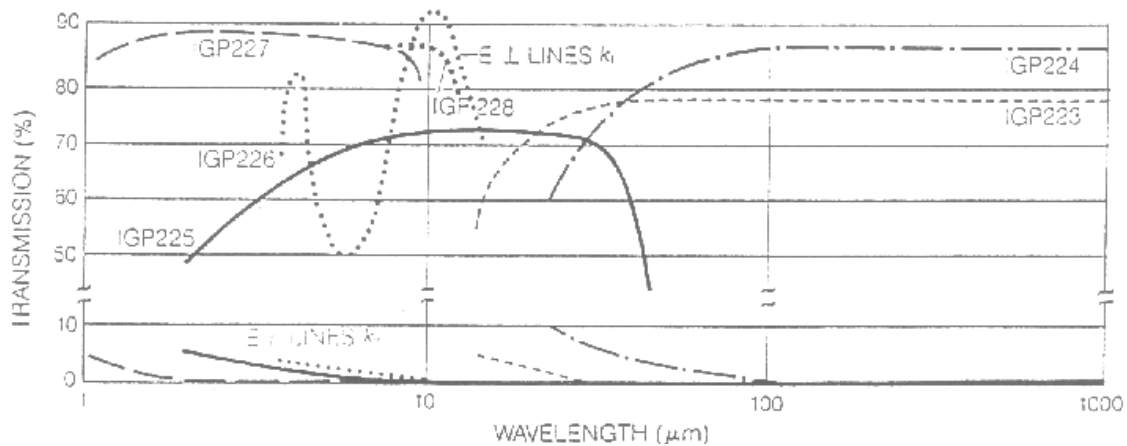

b. Reflecting (due to index change)

1. Brewster angle (stack of plates), each one loses some intensity from (horizontal, ⊥) polarization and transmits all of the other (vertical, ∥) polarization at Brewster angle
Capable of high power, large aperture, modest polarization ratio:

~15% of s polarization rejected at each surface

– in principle the p-polarization is completely transmitted

Prism uses birefringence properties--different index two polarizations —

- o result: total internal reflection of one polarization, other transmit (Glan Prism)
- o one polarization is transmitted with some reflection loss, the other totally reflected (but angle sensitive, narrow angle of acceptance),

a. Glan Taylor has air gap, narrow acceptance angle, ***high extinction ~10^5***, capable of more power, Most-- calcite ($CaCO_3$), due n_x, n_y difference, but absorb far-uv & IR -- far UV : BBO, high power, or rutile, TiO_2, well collimated, small size (5-10 mm)

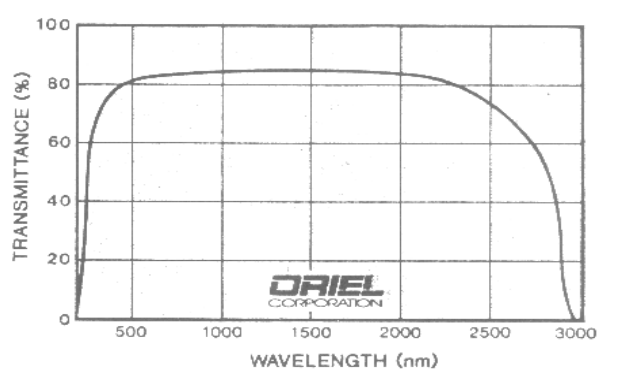

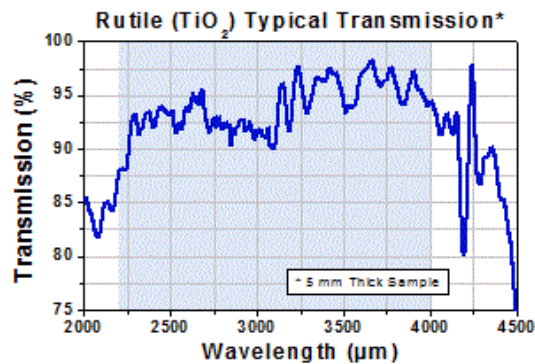

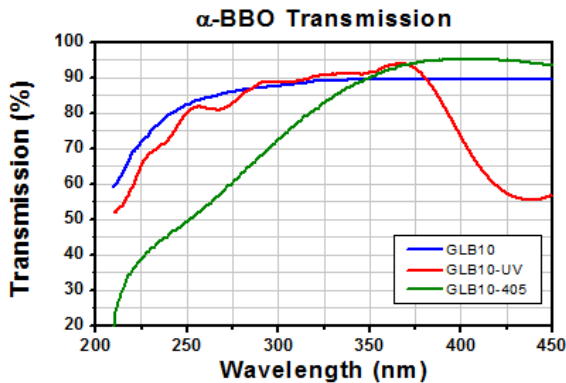

Fig. 1 Oriel Glan-Taylor Polarizer with exit window.

Fig. 2 Transmittance (k_1) of Oriel Standard Glan-Taylor Polarizers for polarized light.

α-BBO Transmission

Rutile (TiO_2) Typical Transmission*

b. Glan Thompson has glue in gap, much larger acceptance angle, lower power, longer λ

c. *Beam splitting prism* (Rochon, Wollaston etc.), transmit both, but divergent angle between polarizations,

if beam is collimated, can separate at a distance,
MgF$_2$ used in vac-uv as Rochon, LiIO$_4$ (goes into IR) sometimes as a Wollaston
.1 Oriel Wollaston Cube Polarizer.

Fig. 2 Beam Deviation and Field Angle vs. Wavelength of Oriel Wollaston Polarizers.

2. Circular polarization

a. Wave plate, slides as example of retardation, use difference in n$_x$, n$_y$ to retard E$_x$, E$_y$

Light Polarization, Birefringent retardation

[courtesy Hinds Inc. brochure]

R$_{lin}$ = 0

R$_R$ = λ/4

R$_L$ = -λ/4

Linear Polarization
Preserved in isotropic medium
Black and Green waves are linear polarizations at right angle, sum to give linear polarization at 45º

Right Circular Polarization **Left Circular Polarization**
Phase retard orthogonal polarizations forward or back with birefringent medium
If shift λ/4→ circular, if λ/2→ linear

Figure 10.6 The optics for making circularly polarized light uses a linear polarizer P and a quarter-wave retarder R. Circularly polarized light can be decomposed into the sum of two mutually perpendicular linearly polarized waves that are one quarter of a wavelength out of phase. With E$_y$ retarded one quarter of a wave relative to E$_z$, we have right circularly polarized light as diagrammed here. If E$_z$ were retarded one quarter of a wave relative to E$_y$, then the circularly polarized light would be left-handed.

-- *birefringence retardation*, δ, depend on wavelength, λ, difference refractive index, Δn = n$_x$-n$_y$
and thickness, z, cause a phase shift of E$_x$,E$_y$ – need both, *input linear polarization at 45°*

$$\delta = (2\pi/\lambda)\ \Delta n\ z$$

-- as light passes through crystal, shift phase of two orthogonally polarized beams (x,y),
when recombine, if λ/4 shift (δ = π/2) then circular (left or right), if δ = π (or λ/2) then
perpendicular linear polarization results–other values give elliptically polarized light

--single plate: λ/4 (circ) or λ/2 (lin), material→Δn, choose z (thin) for λ, Δλ lose pol.
    or multi order: (4n+1)λ/4 - work in narrower Δλ region, easier to make (thicker)
    --"zero order" use two multiorder plates, +(4n+1)λ/4 and -4nλ/4 → result λ/4
--achromat - broader wavelength region - align fast axis of a Multi-Order Crystalline
Quartz Wave Plate to the slow axis of a MgF$_2$ or a UV sapphire wave plate,

--variable – can change index difference by applying stress, static or dynamic,
    stress direction gives retardation add left or right circularity, oscillate—modulator (PEM)

-- [Soliel-Babinet compensator]() - vary z by sliding a wedge into the beam to vary δ
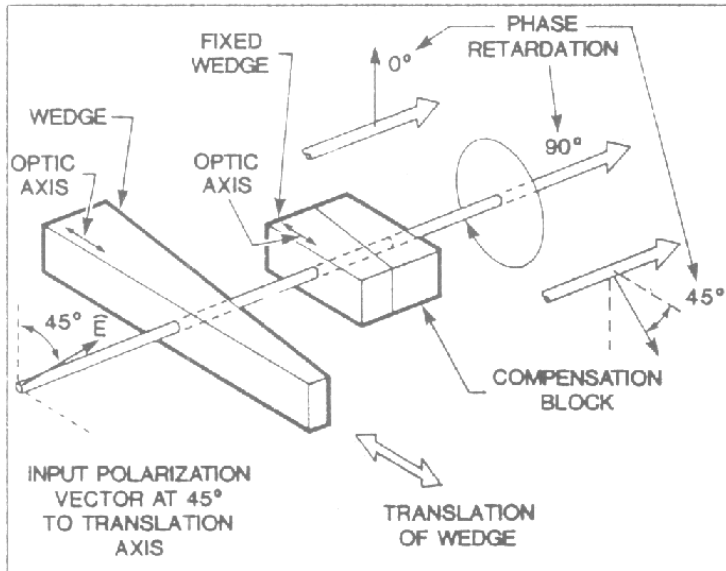

The optics of the Soleil Babinet Compensator. The example shows linearly polarized input radiation and three of the possible output polarizations, 0° retardation giving no change in polarization, 90° or 1/4 wave retardation converting the input to circularly polarized light, and 180° or 1/2 wave retardation rotating the polarization through 90°.

--[Fresnel rhomb]() -- reflection retardation, isotropoic material -- broad band circular polarization
*Relatively large, offset beam, demand collimated light*

RHOMBS FOR UV-VIS-NIR (130nm < λ < 2 μm)
Model No.	Fresnel Rhomb	Air-spaced, Cemented or Optical Contact	Retardation	Aperture	Central Wavelength	Broad Band Coated or Uncoated
	FR	A, C or O*	4 or 2	13 19 or 25	in nm	BB or UN

* ONLY FOR λ/2 RHOMBS

| CENTRAL WAVELENGTH*	MATERIAL	± 2% ERROR RANGE	CENTRAL WAVELENGTH*	MATERIAL	± 2% ERROR RANGE
1080 nm	BK7	500-2000 nm	190 nm	CaF_2	174-205 nm
580 nm	BK7	330-1000 nm	164 nm	CaF_2	154-174 nm
380 nm	FK5	310- 550 nm	148 nm	LiF	142-154 nm
** 272 nm	FUSED QUARTZ	237- 307 nm	136 nm	LiF	130-142 nm
219 nm	FUSED QUARTZ	200- 237 nm			

3. Modulation – *means of improving S/N is signal level low*

a. Characteristics (Figure 1): depth, duty cycle, shape, frequency

Modulation of light intensity

T - period
$f = 1/T$
$depth = \frac{b-a}{b}$
shape – here square
duty cycle $= \frac{on}{on+off}$

This is a square wave modulation with a 50% duty cycle and fairy deep modulation (i.e. b>>a)
    Could be sine wave, triangular, spikes (flash), whatever wanted or device can provide
    Period: $\tau = 1/f$, is the repeat time (inverse frequency) assumed regular (or make noise)
Regularity affects duty cycle: $t_{on}/(t_{on}+t_{off})$, on and off same—50%, more off than on <50%, etc.
Depth: $(b+a)/b$ – affected by "leakage or mechanism for making signal on/off

b. Styles: Chopper mechanical intensity modulation (make dual beam spectrometer)
rectangular holes in wheel — ~square, depend on beam and hole size — circles get ~sin wave
    also can make with tuning fork-triangle or trapezoid, shutter, anything interrupt a beam

alternatively use: polarization, frequency modulation (grating dither)--often sinusoidal
    transient grating (nonlinear effect, crossed laser beams), Interference, acousto-optic

c. Circular/Linear **polarization Modulator**:

-- Electro-optic — induce birefringence with voltage polarization

(e.g. KDP typical, Pockels Cell) - use as a Q-switch in laser common

can switch between linear polarizations ($\lambda/2$ retard) or from linear to circular ($\lambda/4$ retard)

Figure 2. 180° phase shift and 90° rotation of plane of polarization induced by voltage applied to Pockels cell crystal.
--Photoelastic — periodic stress induce birefringence sine wave modulate

Polarization Modulation with PEM for CD
(courtesy Hinds Instr.)

PEM setting:
quarter-wave
retardation ($\lambda/4$)

Polarization
modulation:
right and left
circular
polarization

After the PEM, the light beam is modulated between right and left circularly polarization at the modulator's frequency (1f).

Lock-in reference:
PEM's 1st harmonic
(1f)

Linear Dichroism Schematic (courtesy Hinds Instr.)

PEM setting:
half-wave
retardation ($\lambda/2$)

Polarization
modulation:
bottom || and $\perp$
linear polarization

Lock-in reference:
PEM's 2nd
harmonic (2f)

After PEM, the light beam is modulated between two perpendicular, linearly polarized states at the modulator's 2nd harmonic (2f).
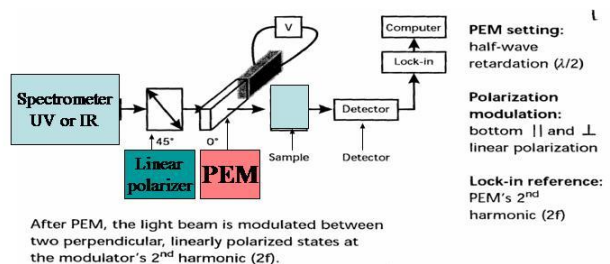

any isotropic material acoustically matched to driver can be basis, wide spectra region possible, results in periodic retardation, sine wave in nature: variable amplitude (see above)

linked slides provide example of CD and LD with polarization modulation

retard wavelength of $\lambda/4$ (right to left circular) or $\lambda/2$ (parallel to perpendicular linear)
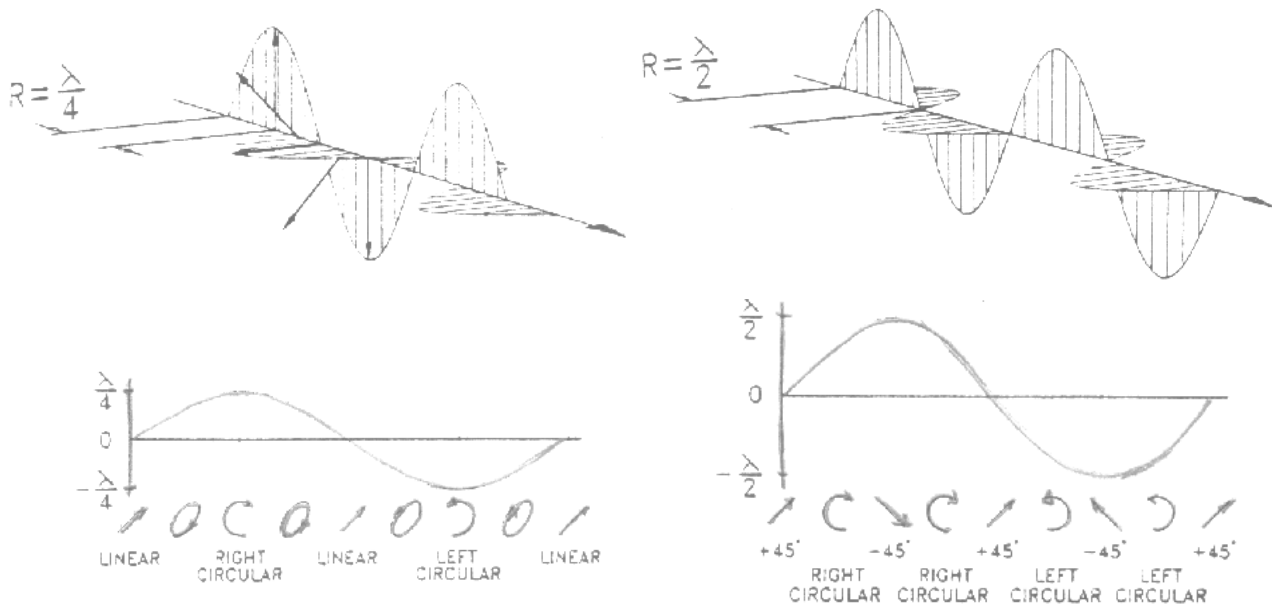

d. Faraday rotator — magnetic field *rotate linear* (not circ.) polarization to new orientation – analogous to optical rotation by chiral solutions, but tunable angle with **B** field

e. Acousto-optic - acoustic wave sets up diffraction for specific wavelength, key -- use deflected beam, maximum modulaton depth

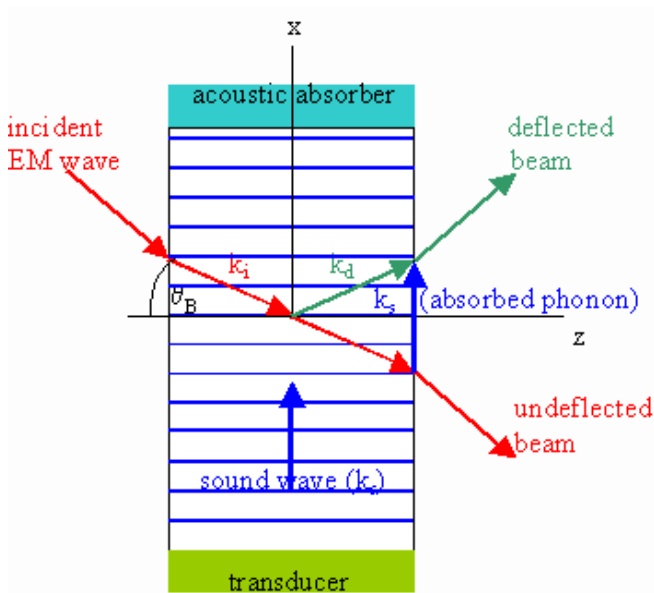

Figure 3. Schematic representation oa a non-collinear AOTF.

An AOTF acts as an electronically tunable spectral bandpass filter. It is a solid state electro-optical device with no moving parts. It

can mode-lock or Q-switch laser, even has been used as basis for a spectrometer
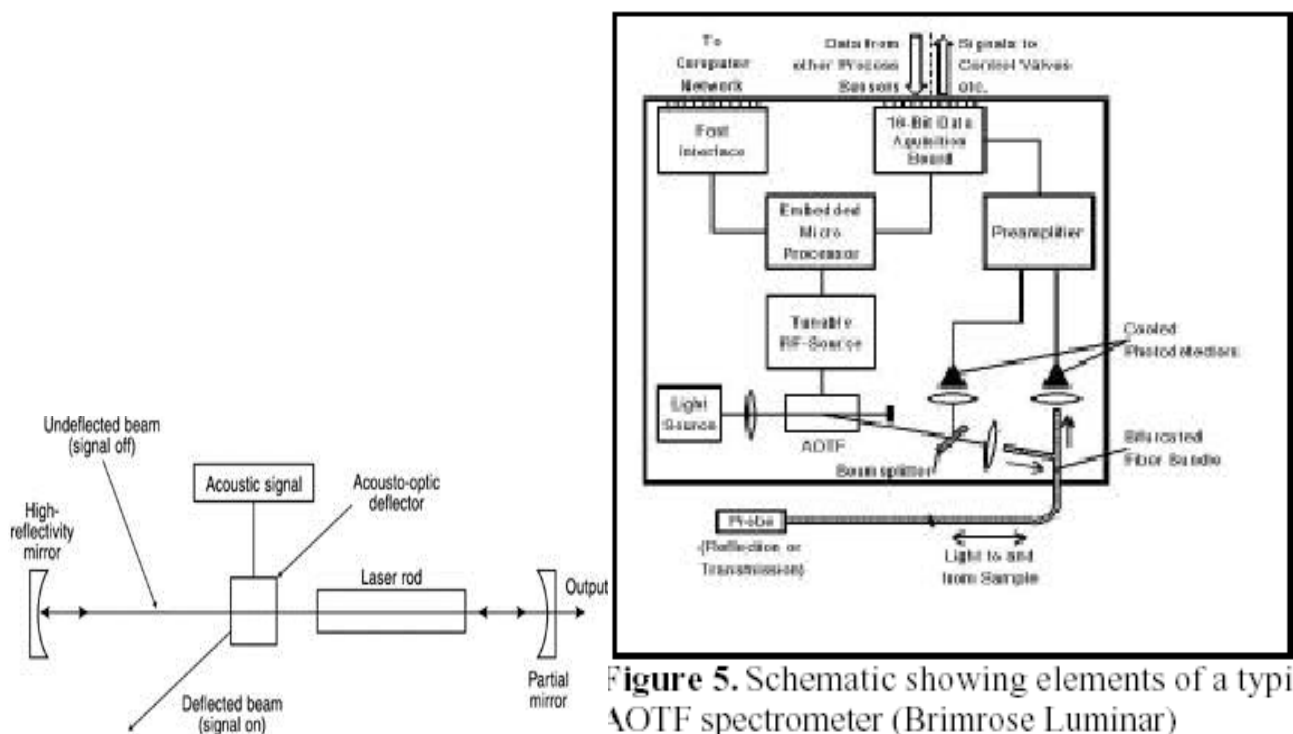

Figure 5. Schematic showing elements of a typical AOTF spectrometer (Brimrose Luminar)

Homework—read in Chap. 3, parts. 1-5 (overlaps previous Section 4, Optics) and

review the modulator tutorials in the links below,

For discussion or thinking (these are important):

1. why are wire grids not useful in vis/uv?
2. why are polaroids not useful in farUV or mid IR?
3. what advantage might a 80% duty cycle modulator have? a 20%?
4. if you can modulate with a simple chopper (cheap, low tech) why go to polarization modulation or shutters or ATOF?
5. what is the difference between a magnetic (Faraday) rotator and a electro-optic modulator (Pockels cell) beyond one uses magnetic and the other electric fields?

Problems to hand in: # 3-14, added to assigned work from section 4 (for Problem set #2)

Plus (look up background data on Web**):**

a. for a wire grid polarizer, if the spacing between wires is 5.0 μm, estimate the minimum wavelength for which you can usefully obtain polarized IR light (e.g. 5:1 ratio)
b. For a calcite prism polarizer, Glan Taylor like, if the cut is at 45°, at what angles of incidence would it be useful as a polarizer (angular aperture is goal)
c. How thick must a crystalline quartz wave place be for $\lambda/2$ retardation at 400 nm and 1 μm for a multi-order plate (choose n = 10) or a single order plate?
d. What is the modulation frequency (Hz) of a wheel turning at 1800 rpm and having 5 holes?
